This is the third post of a four part series describing how to clone a Docker container in C# using dotnet cli. (previous articles) Last week I learnt how to create a new Docker container using the dotnet cli. Today I'm going to show you how to use that container to run and test some C# code. I'm going to implement a simple example using a .net core console application. The first thing we need to do is create a Dockerfile that will allow us to run an .NET Core application. This is a minimal Dockerfile that will allow us to run a console application, I'm not going to cover the the Dockerfile syntax in this post. The Dockerfile is just a plain text file that has a shell command that runs a CMD followed by a little bit of Dockerfile magic. The Dockerfile runs commands like FROM that create a new container. The CMD allows you to specify any container command that will run before you run any commands that you have defined in your docker compose or docker run command. In this case the application will print Hello world. CMD ["dotnet", "ConsoleApplication.dll"] Now that we have the Dockerfile set up we can write a .NET Core program that will run the container, do something and exit. This is my application called HelloWorld. I start a new .NET Core console application and rename the project to match the Dockerfile name. I then add a new class called HelloWorld.cs to the project. (Feel free to add other classes or even modify the HelloWorld.cs file to suit your requirements) . Next I run the following command: dotnet new console -o "HelloWorld" -r "Dockerfile" I then add some code to the HelloWorld.cs class that will create a container (run a console application) and print some hello world text, call exit and force dotnet to exit. Then I run the following command: dotnet run -p "5000" We'll then see the container print out some hello world text. docker 50b96ab0b6

Technical Support How do I register for UserVoice? When you sign up, you'll be able to submit ideas and vote on them. You can also create tags to help customers find the types of issues that are more important to them. Taxonomic revision of the genus *Vulsotoma* Oldham in Taiwan (Cladocera: Daphniidae). The daphniid genus *Vulsotoma* Oldham, 1802 is revised in Taiwan and Singapore. Three new species, *Vulsotoma motoana* Zun et He, sp. n., *Vulsotoma parviana* Zun et He, sp. n. and *Vulsotoma pulchra* Zun et He, sp. n., are described. All records of *Vulsotoma orientalis* (Krapovickas, 1974) from Taiwan and Singapore are invalid. The genus is revalidated under *Vulsotoma Chien*, 1955, with five species in Taiwan and two in Singapore. *Vulsotoma gerograpti* Zun et He, sp. n. is a new record for Taiwan. All of the species of Taiwan and Singapore are redescribed. The new species *V. motoana* sp. n. and *V. parviana* sp. n. differ from each other and from *V. orientalis* by various characters such as the lateral wing processes and the size of the frontal and caruncle. *V. parviana* sp. n. and *V. gerograpti* sp. n. are similar in the shape of the cephalic process, the first discal dorso-lateral caruncle, and the fore wing apex, but differ in the third discal dorso-lateral caruncle, the size of all caruncles and the structure of the hind wing. The taxonomic status of the species of Taiwanese and Singaporean *Vulsotoma* remains unclear. Echocardiography in neonates: are the views of the aortic valve and the ductus arteriosus replaced by blood flow? Evidence that blood flow through the heart affects diastolic flow through the aortic valve and the ductus arteriosus can be found in the literature. This finding implies that views of the aortic valve and the ductus arteriosus in neonates are more dependent on blood flow than views of the left ventricle, mitral valve and right ventricle, which are more affected by contraction
