But there are several problems with the solutions given by the book. And my equations aren't giving correct solutions as they are not the same as the book. Is there any other better method of solving this problem? Or has the book given a wrong method?

Why are these two solutions for the last row incorrect? Why did the book give the solution to the right most column? Is it correct? Here is the wrong solution. I have attempted to find the correct solution but couldn't. Can anyone help me in finding the right solution? A: If you look at the book solution you see that the result is correct (to the extent that it is possible), but I believe

the problem you are dealing with is the one on the second page. I have no idea if this is a typo or not, but I will give my best guess. I assume you need to find  $x_2$ ,  $x_3$ , and  $x_4$ . If so, write the equation for the last row in the matrix. You will have a system of equations for  $x_2$  and  $x_3$ , which is not hard to solve if you know what to do. However, you will also need to know  $x_4$  to solve for it. Fortunately, you do not have to solve a new equation for  $x_4$ ; you can use the original equation to solve for it. If you do this, you should get  $x_4 = -17/3$ . Another way to see this is to rewrite the equation for the last row using the other equations, which gives you  $3x_1 + 7x_2 + 11x_3 = -1$ . Solving for  $x_1$  in this equation gives  $x_1 = 6$ . This tells you that  $x_2 = -6$ . You can then solve for  $x_3$  in the original equation by multiplying this result by  $-1$ , which gives  $3x_3 = -4$ . Solving for  $x_3$  then gives you  $x_3 = -1/3$ . Finally, you can solve for  $x_4$  in the original equation by multiplying the last result by  $-17/3$ . Solving for  $x_4$  then gives you the answer you are looking for. You should use the book's solution as a guide, but 82157476af
